

Unit 1

ANALYTICS IN SOCIAL MEDIA AND TYPES OF ANALYTICS TOOLS

Unit 1

ANALYTICS IN SOCIAL MEDIA AND TYPES OF ANALYTICS TOOLS

Syllabus

- The foundation for analytics, Social media data sources, Defining social media data, data sources in social media channels, Estimated Data sources and Factual Data Sources, Public and Private data, data gathering in social media analytics.

Contents

1. Foundation of Analytics

1. Foundation of Analytics

Future Success of Marketing

- Data about our company,
- Data about our consumers
- Data about our market
- Data about the world

Analytics Based on

- Use of Data
- What data is
- How it can be used
- Effectively add analytics

Technical Challenges

- Data is not only created by humans in the world, but also by machines
- Data created grows almost out of control
- New challenges in terms of storage and accessibility

1. Foundation of Analytics

- Data is information
- Objective
 - To enhance any given process
 - To change something for better
 - To improve upon a current condition

1. Foundation of Analytics

Or data
as a
storage
unit for
piece of
informati
on.

Someone hits like button on
social media page

This action generates data

Technology makes use of this
data/storage units

To access this information they generate an
output that fulfills an objective such as
delivering a graph showing how many likes a
piece of content received over time.

2. Social Media Data Sources

Knowledge of Data Sources: An Example

I wish to see all the mentions of my brand on the Internet, separated by geographical region, and including the demographics of the people making the mentions, plus an analysis of the relevance of the people mentioning, and if my competitors are also mentioned

Knowledge of Data Sources: An Example

Point out different needs :

- All the mentions of brand on the Internet,
- Geographical region,
- With demographics,
- The relevance of the people mentioning,
- If the mentions include competitors

Knowledge of Data Sources: An Example

Point out different needs :

- All the mentions of my brand on the Internet:
 - The Internet is a vast space,
 - and tools will likely miss a few mentions of the brand.

Knowledge of Data Sources: An Example

Point out different needs :

- Geographical region,
 - Reduce the sample of mentions
 - Many mentions will not provide a clear indication of the region

Knowledge of Data Sources: An Example

Point out different needs :

- With demographics:
 - Mentions have to be connected to user profiles that include the age, gender, and other information about a person making a mention

Knowledge of Data Sources: An Example

Point out different needs :

- The relevance of the people mentioning
 - Relevance is subjective
 - how interactions and conversions by potentially relevant people or partner channels are generated

Knowledge of Data Sources: An Example

Point out different needs :

- If the mentions include competitors
 - start by listing the competitors

3. DEFINING SOCIAL MEDIA DATA

what social media data is and what it is not?

social media data as data generated within a self-named social media platform

3. DEFINING SOCIAL MEDIA DATA

- Platforms such as
 - Facebook
 - Twitter
 - LinkedIn
 - Instagram
 - Google+,
 - YouTube
 - Pinterest
 - Snapchat and others.

3. DEFINING SOCIAL MEDIA DATA

- The main focus is not to tackle every single specific point of every network,
- but instead to develop your knowledge to a level where you can tackle any of these networks as targets of your marketing strategies,
- and be ready for cross-network strategic planning and analysis.

4. Data sources in Social Media Channels

The following are common human social media actions

- Create a profile.
- Publish content.
- Praise or react to content (e.g., likes, favorites, etc.).
- Comment on content.
- Share content.
- Create groups and content only available to the group.
- Send direct messages and chat with other users.
- Connect to another profile (as a friend, follower, etc.).
- Purchase products and perform transactions

4. Data sources in Social Media Channels

- There are different details in these common features from one social network to the next.
- The following are a few examples:
 - Fields for creating the user profile
 - Limitations and regulations over content interaction and visualization
 - Content types that can be published
 - Methods to send messages or to *tag other users*

4. Data sources in Social Media Channels

- The user features also have a different effect on the other platform features.
- For example, that a “like” on Facebook generates a different exposure to the content than a “like” on Pinterest or Instagram

Estimated Vs. Factual Data Sources

Estimated metrics include views, impressions, and reach, for example, which provide the number of times a user has potentially seen a certain piece of content or advertising.

Estimated Vs. Factual Data Sources

As an example, let's take two days in content promotion (investing the same amount of money):

- Day 1 results: 500 impressions, 30 conversions
- Day 2 results: 500 impressions, 50 conversions

- With the same number of impressions as a reference day 2 had more conversions.
- Neither impressions alone, nor conversions alone would have given this view.

Estimated Vs. Factual Data Sources

The understanding and relationship between estimated metrics and factual metrics will be part of the core of current and future strategies in social media and social media analytics.

6. Public and Private Data

6. Public and Private Data

- So if we are looking for competitive analytics and social media benchmarking, which is really a must-do for optimizing social strategy, we need public data for that.
- Public-level data allows us to see the performance of our competitors' social media channels, or any of the available information that does not belong to us.

Two points are important to remember:

- What is public can be easily compared.
- What is private, if it does not belong to us, can only be estimated.

6. Public and Private Data

- understand that paid detection does not come from the same data source as private data; it is not the private information being revealed.
- It is a new data source coming from the intelligence of the machine learning system—so that you can get data sources covered.

7. Data Gathering

Data can be gathered in two ways when it comes to pulling human-action information from social media platforms:

**Via API
(application
programming
interface)**

**Web crawling
or scraping**

Social Media Network Support of Data Collection

7. Data Gathering

Data can be gathered in two ways when it comes to pulling human-action information from social media platforms:

**Via API
(application
programming
interface)**

**Web crawling
or scraping**

Via API (application programming interface)

- This structure points the programmer straight to the data that he or she is looking for
- Facebook offers API access to its data. A programmer can look into Facebook and request any specific information; for example, “total likes for a certain page post” Facebook then shows the programmer exactly where the number of the “total likes for the post” is located inside their database, and the programmer can then easily get that information

Via API (application programming interface)

- The programmer can then safely add to the program the places where the data is stored inside any application that the program is trying to access because the data will always be in the same spot.
- With this safe and reliable access, the programmer can then work on the program, so that it can always find the data from the other application it is connecting with.

Web Crawling or Scraping

- Source Code
- A good-looking web site full of images has a set of hidden instructions telling the browser how to display all that information.
- A programmer can tap into the source code and then *crawl for any specific* information needed.
- Other term: *scraping*.
- Fragile and unstable way of gathering data,
 - because when anything changes on the web site, the source code is changed,
 - and the programmer has to reprogram a new way to *crawl for the information*.
- It is also likely that *crawling can bump into privacy regulations from web sites*;
- So whenever possible, API access is the way to go. APIs are what most analytics platforms rely upon.

*Thank
you*
